

The why and how of assessing pain and suffering in animals

Dan Weary

Part 1: Methods used to draw inferences regarding felt emotions?

- Acute response to noxious stimuli
- Responses with and without targeted drugs
- Motivation and conditioning tests
- Drug discrimination and generalization

Part 2: How do such feelings contribute to the experience of suffering?

Acute response to noxious stimuli: e.g. heel prick in infants

Acute response to noxious stimuli: e.g. uterine palpation in metritic cows

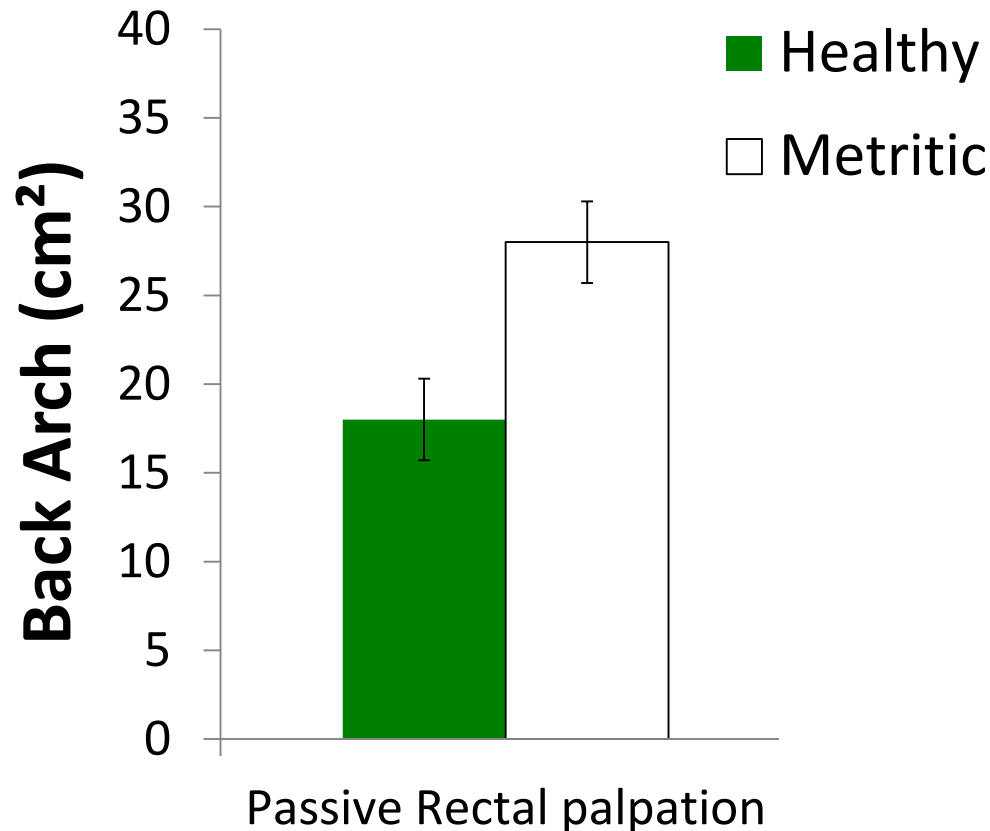

Before palpation

During palpation

Acute response to noxious stimuli: e.g. uterine palpation in metritic cows

Acute responses to noxious stimuli are intuitively compelling, but:

- Responses may not be pain specific
- Both response and lack of response can be difficult to interpret

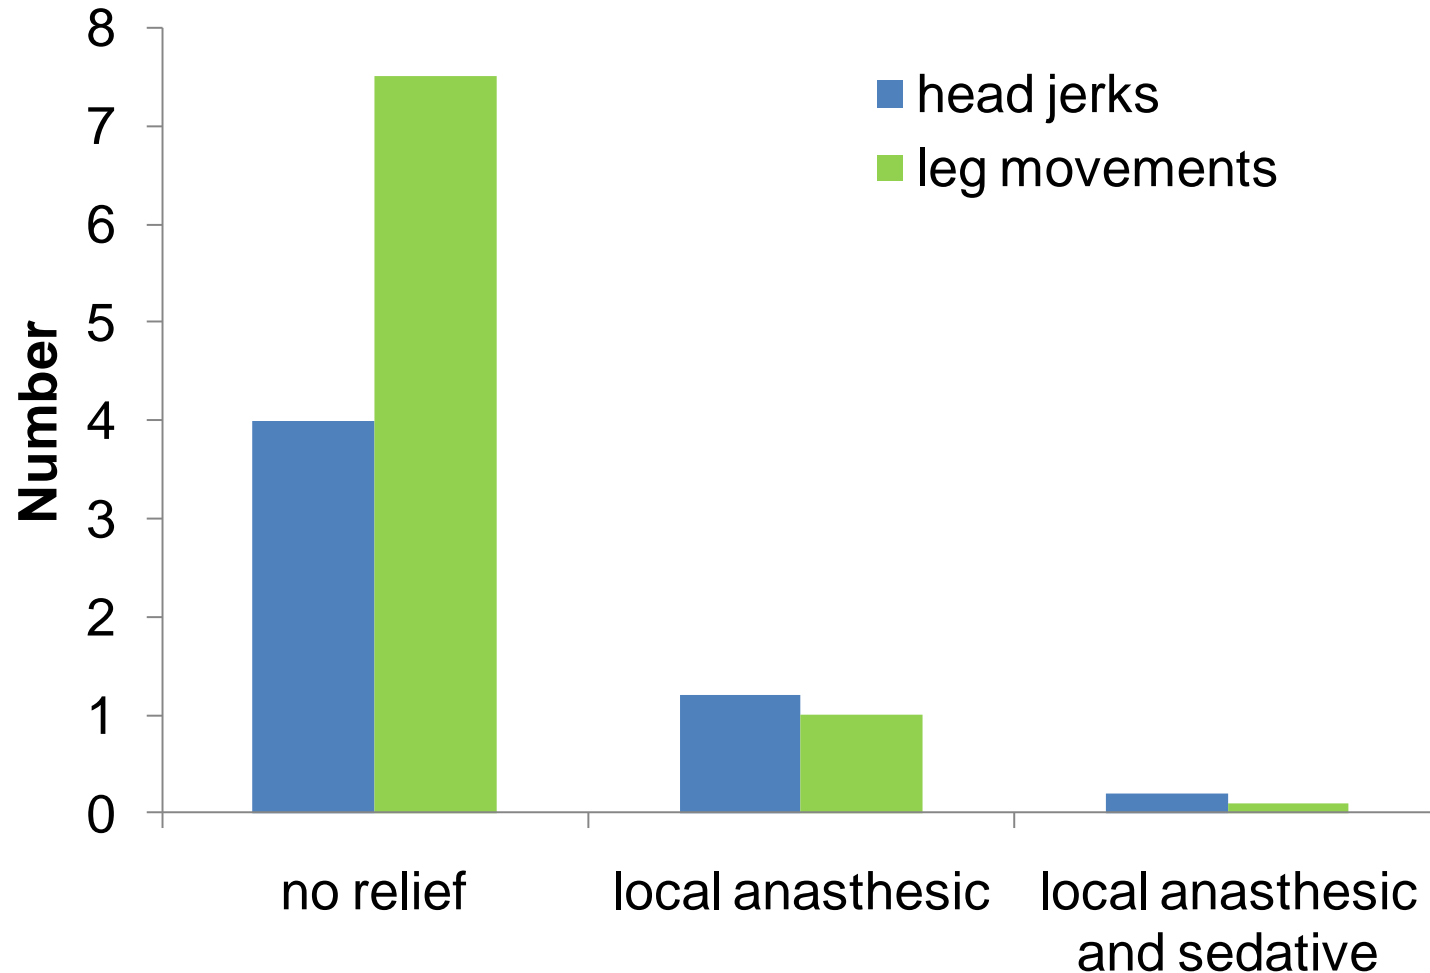

Part 1: Procedures used to draw inferences regarding felt emotions?

- Acute response to noxious stimuli
- **Responses with and without targeted drugs**
- Motivation and conditioning tests
- Drug discrimination and generalization

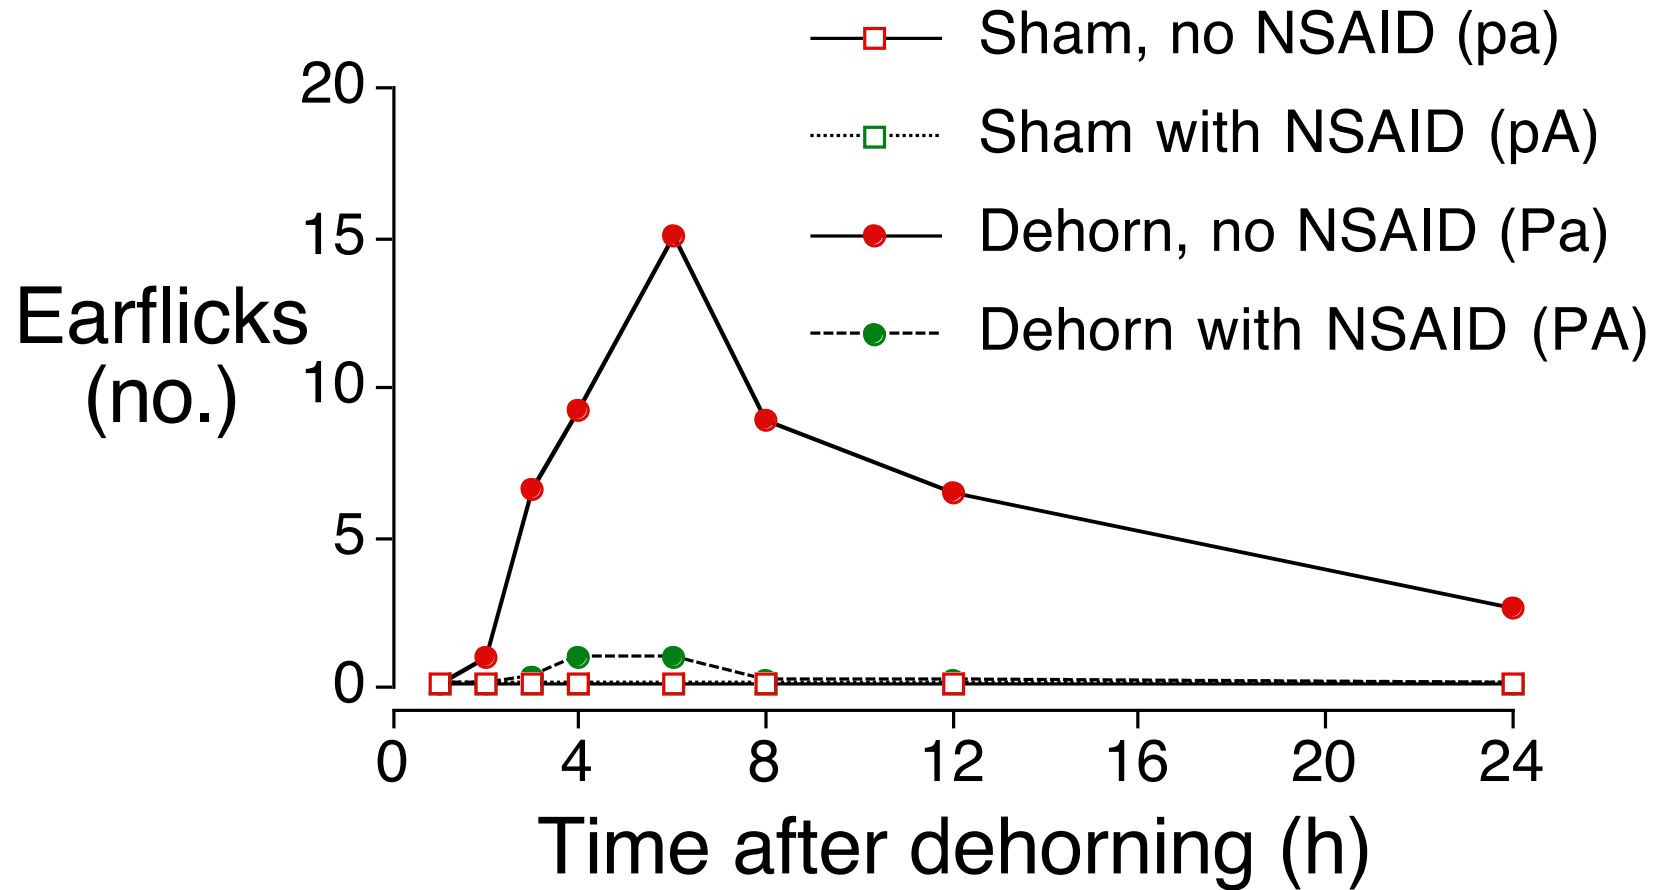

Pain control: e.g. Intra-operative pain

Pain control: e.g. post-operative pain

Acute responses to noxious stimuli are intuitively compelling, but:

- Responses may not be pain specific
- Both response and lack of response can be difficult to interpret

Part 1: Procedures used to draw inferences regarding felt emotions?

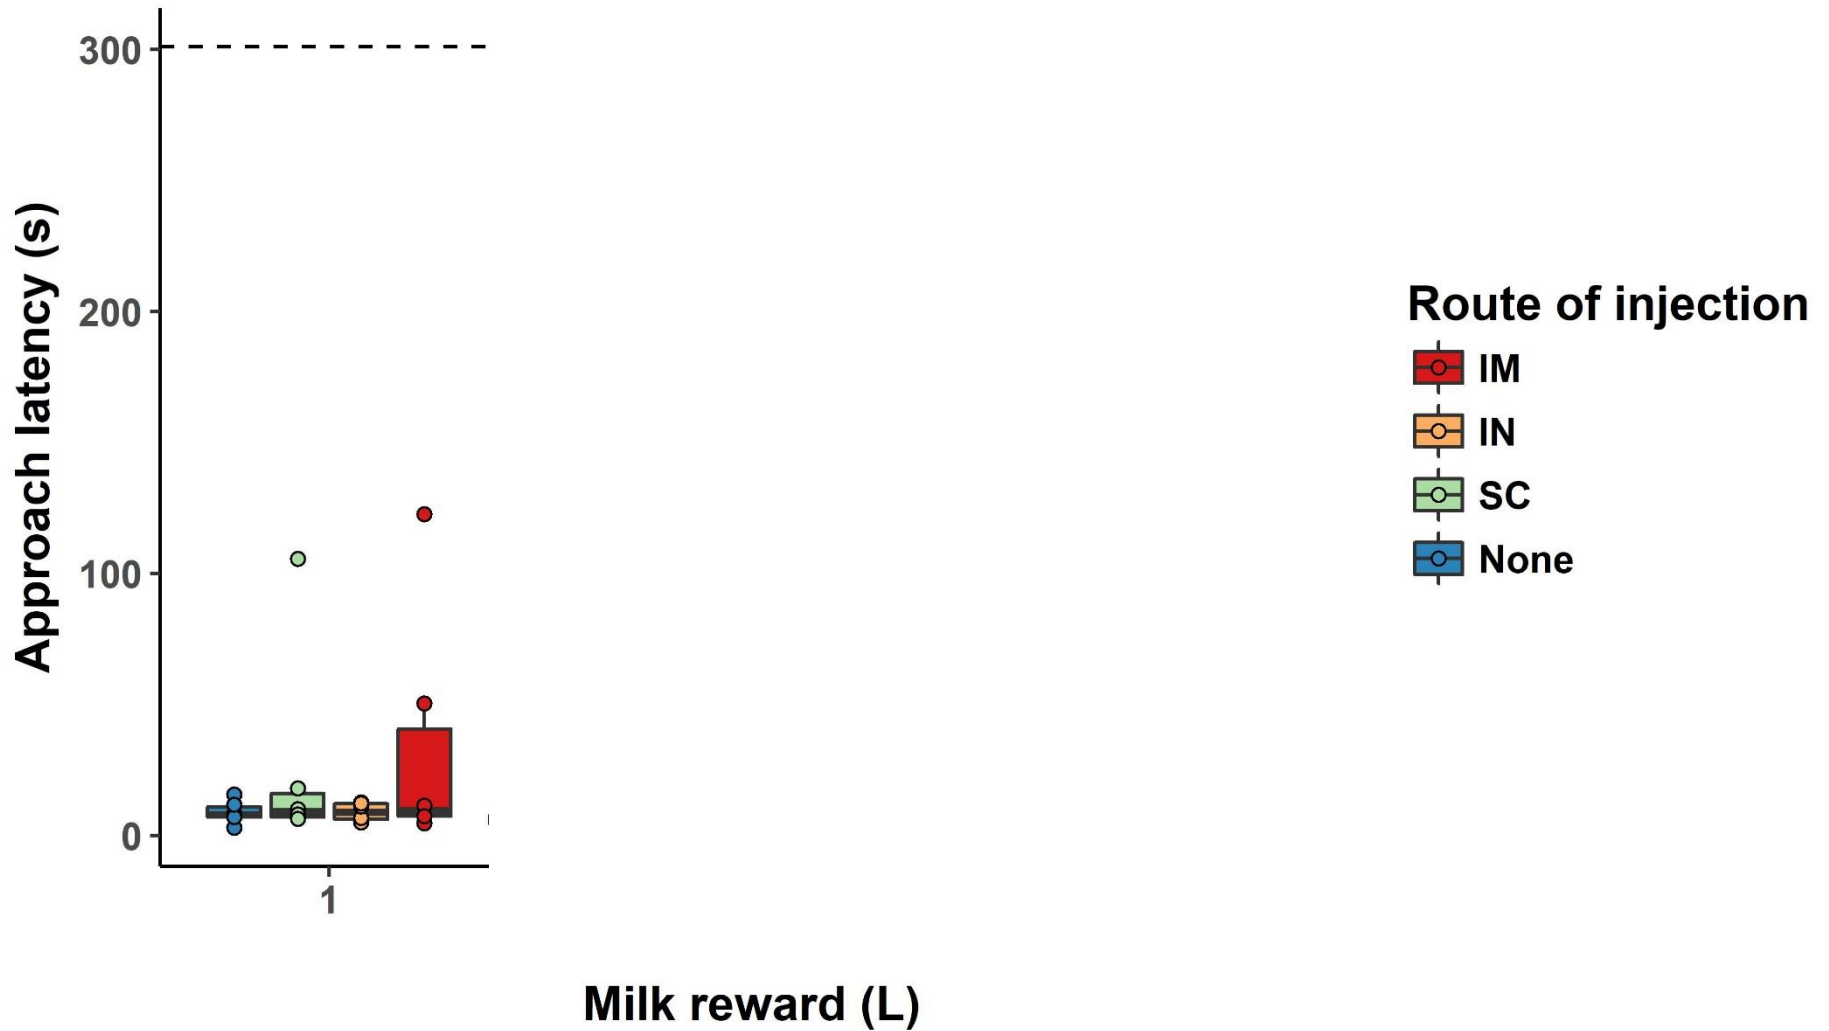

- Acute response to noxious stimuli
- Responses with and without targeted drugs
- **Motivation and conditioning tests**
- Drug discrimination and generalization

Approach-avoidance testing

Injection method:

Approach-avoidance testing

Motivational tests provide pre-defined response measures with high consistency, but:

- Require inferences about motivation to access reward
- Motivation may vary with type of reward
- Some tests rely on an acute response (e.g. withdraw/escape)

Conditioned place aversion

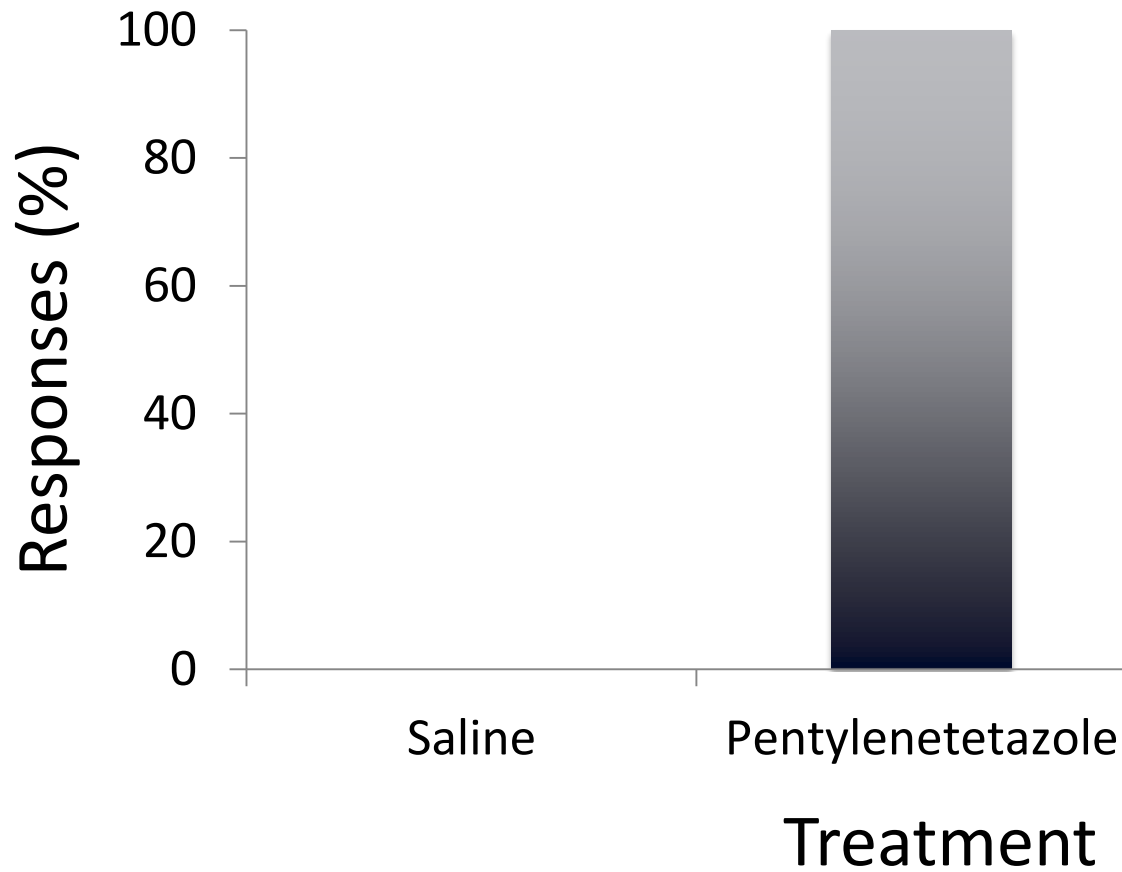

Conditioned place aversion

Part 1: Procedures used to draw inferences regarding felt emotions?

- Acute response to noxious stimuli
- Responses with and without targeted drugs
- Motivation and conditioning tests
- **Drug discrimination and generalization**

Drug discrimination and generalization: e.g. rats on PTZ

Inferences regarding felt affect?

Response measures

Functional, specific,
consistent

Function unclear, non-
specific, variable

Design features

Drug discrimination and
generalization

Motivational testing

Analgesics and controls

Response to noxious
stimuli

Part 1: Procedures used to draw inferences regarding felt emotions?

Part 2: How do such feelings contribute to the experience of suffering?

Usage in the medical literature

concurrent negative affects:

The patient required “small doses of codeine” for pain when she thought it was due to sciatica, but much higher doses were required when she was diagnosed with cancer.

Usage in the medical literature

concurrent negative affects:

“In the month between an irregular chest X ray and results of the biopsy, I enjoyed very good health in the presence of serious illness... this turned that month into a controlled experiment in pure suffering.”

Usage in the medical literature
concurrent negative affects:

“The tendonitis caused extraordinary pain ... but I knew what was happening and had reasonable assurance that the acute phase would not last long... So here is the reverse experiment: pain with more annoyance than suffering.”

Usage in the medical literature

Mood state:

Reduced ability
to perform
highly
motivated
tasks

Low mood

Usage in the medical literature

Anhedonia:

Reduced
motivation to
perform
previously
rewarding tasks

Low mood

Usage in the medical literature

Loss of control:

“Suffering can start with anguish over the possibility that if the symptom continues, the patient will be overwhelmed or lose control”

Applying this understanding to animals?

concurrent negative affects:

e.g. pain + fear

anhedonia:

Evidence of anhedonia:

- reduced appetite
- reduced grooming
- reduced anticipatory behaviours

Assessing mood:

Training task

Cognitive Bias Task

*Do calves approach these
ambiguous screens?*

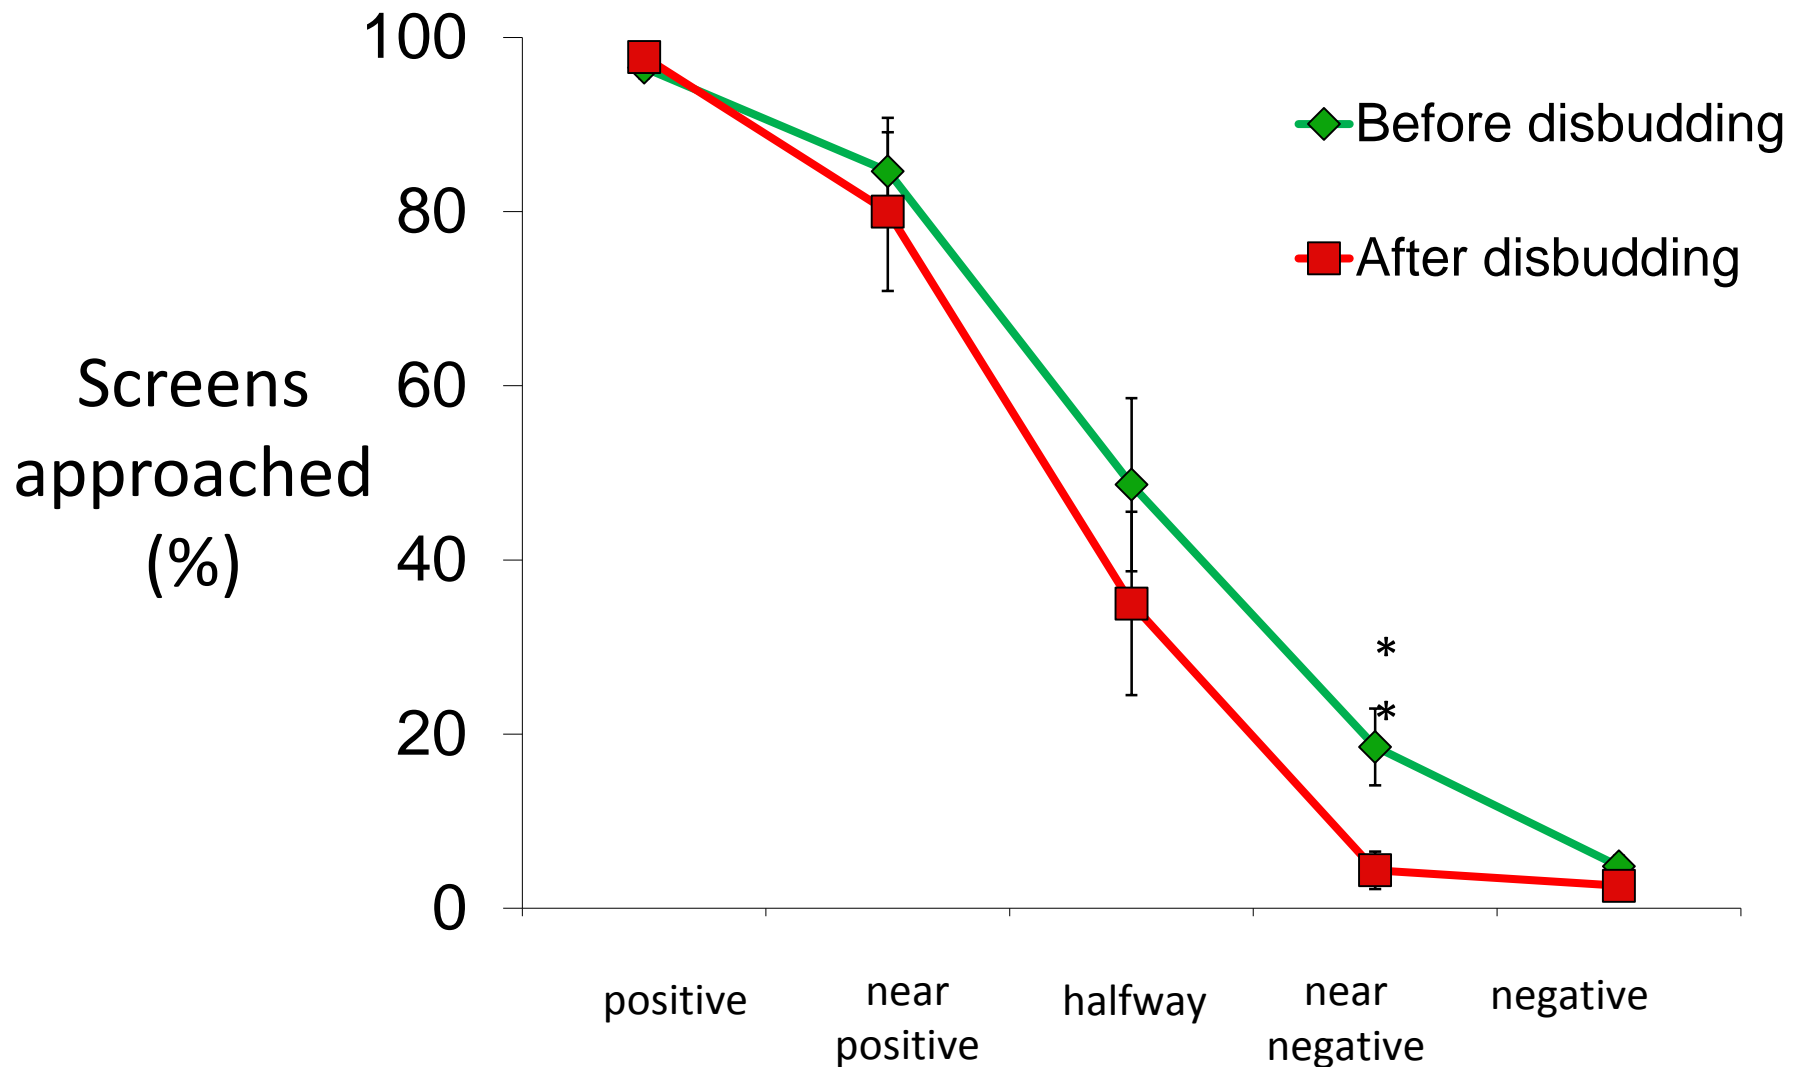

Generalization curve

Control:

Suffering summary

Pain is more likely to contribute to suffering when combined with:

- Fear
- Lack of control

Suffering might be identified by:

- Reduced performance of motivated behaviours
- Other indicators of low mood
